Linuxdoc Reference

A introduction to the linuxdoc dtd

Uwe Böhme, <uwe@hof.baynet.de>

v1.1, 30 January 2000

This article is intended to be a reference for the SGML document type definition linuxdoc, which is coming along with the SGML text formatting system version 1.0. It should also be applicable to future versions which may be found at My Homepage.

Appendix

1. Making of

1.1 Legal stuff

This document is not part of *ldp* (even if I took their form of license). I'm not yet playing in that league.

1.2 Genesis

This document was born trying to learn more about writing texts on my linux system. The one system looking like suitable to my needs was sgml-tools SGML-Tools Organsation an the linuxdoc dtd.

In [*SGML-Tools User's Guide 1.0 ($Revision$)*] (see section Reference) the overall structure is described nice and easy. Also [*Quick SGML Example, v1.0*] (see section Reference) was helpful, **but**:

A lot of features are not mentioned.

On the way to learn more about it, I met [*The qwertz Document Type Definition*] (see section Reference). It's as detailed as hoped, but it's not made for the linuxdoc dtd (even if linuxdoc is based on qwertz).

I tried a new approach: Look at the dtd

> dtd = document type definition

file itself, and try to understand it.

As time went by I noticed that I also forgot about some stuff, or - at least - didn't point it out strong enough. This will change within the next revision.

Any feedback you might have is welcome (especially help with English spelling or grammar) by e-mail at Uwe Böhme.

2. Introduction

The principle of any sgml'ed document (linuxdoc, docbook, html) is more or less the same:

Don't write how it should *look like*, but write what it *is*.

This is a different approach than the standard "wysiwyg"

> What you see is what you (should) get (if you are a very lucky one and your computer wins the war against buggy software)

one

> You might want to call it `wysiwym`, i.e. "What you see is what you mean"

. You do not tell the program that this line should be in a bigger font, **to look like** a headline. What you do is telling that this line **is** a headline. You do not try to make your document **look like** a report, but you tag it **to be** a report. So you *tag* the text with the appropriate <tag>.

The big advantages of this approache are:

1. You do not need to mess around with fontsetting, line gaps or anything directly connected to the layout.
2. You describe your document in a more abstract way so it's more reusable and can be mapped to different media types.

> If you ever tried the reuse a document written in a specialized wysiwy layout for html then you know what I'm talking about.

In addition in all sgml-style documents you will find named symbols This is a concept to expand the charset of the document and to avoid inconsitences in decision of the parser, how to interpret or map some special characters.

How should the parser know weather a < character is starting a tag or should be printed directly. This is solved by the named character *lt*. If you write `<` this one will result to < in your text. For a list of the named symbols see Named Symbols.

Hint for the new user

> It might be a good idea, to download this document not only as a dvi or ps document, but also to download the sgml source. This offers you the chance to look into the sources, if you find something within this article, wich might fit your needs.

3. A minimalistic document

In this section you'll find what you'll need for a minimalistic linuxdoc dtd conform document. It's intended to give a first touch. Skip this section, if you already now the principles.

3.1 Step By Step

The steps you have to do to create a nice linuxdoc document and map it to the form you need are:

- Take a plain text editor of your choice.
- Create a file and name it (or later save it as) e.g. `start.sgml`.
- Type the document
- Save the file and close your editor.
- Run the checker by typing `sgmlcheck start.sgml`.
- If you get errors reported, reopen your document in your editor again and try to correct it

    The error messages of `sgmlcheck` will give you a hint about the type of error and also line and column where it occurred.

  . Run the checker again until no more errors occur.
- Now you have to decide what's your document for. Take the apropriate parser mapper combination and translate your document. To find the mappers available in the SGML-Tools see table SGML-Tools mappers for sgml documents.

type	to produce
`sgml2html start.sgml`	Hypertext markup language for web browsers
`sgml2lyx start.sgml`	Lyx or KLyx wysiwym textformat
`sgml2info start.sgml`	Info page for UN*X info
`sgml2latex start.sgml`	DVI output
`sgml2latex --output=tex start.sgml`	pure tex output
`sgml2latex --output=ps start.sgml`	postscript output
`sgml2rtf start.sgml`	rich text format
`sgml2txt start.sgml`	pure text

SGML-Tools mappers for sgml documents

3.2 A Startup Document

We start with a simple document (the numbers and colon in the beginning of the line are for explanation, don't type it!):

```
1: <!doctype linuxdoc system>
2: <notes>
3: <title>A Small Linuxdoc Example</title>
4: <p>Hello <em>world</em>.</p>
5: <p><bf>Here</bf> we are.</p>
6: </notes>
```

Now we take a look at the single lines:

1. A linuxdoc document has to start, like all SGML conform documents, with the *preamble*. If you like you can take it as a piece of necessary magic, or you can try to find more information about SGML. The preamble is indicating to the SGML-parser, which dtd (document type definition) it should use for checking the syntax of the document.
2. Open the *document class*: You have to decide, wich type of document you want to write. See section Document Classes for detailed description about that *document classes*. The necessary header information, wich is depending on the *document class* is also explained there. In our case we place a `<notes>` tag forming a note, wich is indicating a simple unstructured document.
3. Even if optional it's a good idea to give a *title* to the document. That's done with the `<title>` tag.
4. A paragraph marked by the `<p>` tag, containing the word `world` wich is *inline emphasize*d by the `<em>` tag.
5. Another completely tagged paragraph, with another word *inline boldface*d by the `<bf>` tag.
6. Here we close the open *document class* tag.

The same example may be written a little bit shorter, by leaving out tags which are placed automatically by the parser, and by using shortened tags:

```
1: <!doctype linuxdoc system>
2: <notes>
3: <title>A Small Linuxdoc Example
4: <p>Hello <em/world/.
5:
6: <bf/Here/ we are.
7: </notes>
```

Now we look at the single lines again:

1. The *preambel*.
2. The document class (also unchanged).
3. The *title*. It's not closed, because the `p` tag in the next line is implicitely closing it.
4. The paragraph is implicitly closing the *title*. The *emphasize* tag is noted in short form. The short notation you can use only if your tagged text doesn't contain a litteral `/`. The *paragraph* is not explicitly closed in this line.
5. The empty line here is the reason, why you don't need to close the previous *paragraph* and don't need to open the next one. A empty line is interpreted as a end of the current paragraph and the start of a new one.
6. Another paragraph (not opened directly), with another short *inline* tag.
7. Closing the open *document class* tag, wich is implicitly also closing the still open paragraph.

Maybe now it's a little bit more clear, who you have to work with tags.

4. Document Classes

```
<!element linuxdoc o o
        (sect | chapt | article | report |
         book | letter | telefax | slides | notes | manpage ) >
```

This is describing the overall class of the document, so naturally it has (leave alone the doctype definition) to be the first tag enclosing your whole document. Some of the tags namely the `sect` and `chapt` (see section Sectioning Tags) doesn't make any sense taken them standalone despite being included as part of more complete classed document, so we'll describe them later as a part of the other document classes. Decide first

which of the top mentioned document classes fits the type of the document you want to write best.

To find a detailed description of the document classes see table Document classes.

Chapter	Class tag
Article Tag	<atricle>
Report Tag	<report>
Book Tag	<book>
Letter Tag	<letter>
Telefax Tag	<telefax>
Slides Tag	<slides>
Notes Tag	<notes>
Manpage Tag	<manpage>

Document classes

To me the *article class* is the most important one. That´s the reason why it´s described first and most detailed.

4.1 Article Tag

```
<!element article - -
         (titlepag, header?,
          toc?, lof?, lot?, p*, sect*,
          (appendix, sect+)?, biblio?) +(footnote)>

<!attlist article
         opts cdata "null">
```

You can see that the *article* needs some tags included. They will be explained in consequence.

The *options* attribute (`opts`) takes a comma separated list with thy different style (LaTeX `.sty`) sheets to inlude within the document.

Titlepage Tag

```
<!element titlepag o o (title, author, date?, abstract?)>
```

The *Titlepage* Tag (`titlepag`) is implicitly placed as soon a you started your *document class*. You don't need to write it explicitly. Anyway you have to note it's mandatory tags. It's purpouse is to describe the layout and elements of the titlepages.

Title Tag

```
<!element title - o (%inline, subtitle?) +(newline)>
```

Each *document class* wich owns a titlepage of course needs a *title*, wich is noted down with a <title> tag. You don't need to close thatone. A title may contain a *subtitle* started by the <subtitle> tag.

If you look at the headerpage of this document you'll find it to be mapped from the tags:

```
<title>Linuxdoc Reference
<subtitle>A introduction to the linuxdoc dtd
```

Author Tag

```
<!element author - o (name, thanks?, inst?,
                        (and, name, thanks?, inst?)*)>
```

Usually you place the (your) name here. People should know who wrote the document, so you place a <author> tag. If you don't note the name tag it´s imlicitly placed. The *author* has also optional items wich can be tagged within the author tag.

If you want to say thanks to anyone (might be somebody providing usefull information) you place it within the <thanks> tag. Next, if your writing is done in your position of an *institution* staff member, place it within the <inst> tag.

The <and> tag is starting the whole story again, as if there would be a second author tag would have been started. Clearly thisone is for coauthors.

Date Tag

If you want to mark your document with a *date*, you can do that with the <date> tag.

> It's not checked weather you really place a valid date here, but don't abuse it.

Abstract Tag

This tag is intended for an *abstract* description of your document. Don't mix the <abstract> tag withh an *indruduction* wich is likely to be placed inside the first *section* of your document (see section Sectioning).

Header Tag

```
<!element header - - (lhead, rhead) >
<!element lhead - o (%inline)>
<!element rhead - o (%inline)>
```

A <header> tag specifies what should be printed at the top of each page. It consists of a *left heading* i.e. <lhead> and a *right heading* i.e. <rhead>). Both elements are required, if a heading is used at all, but either may be left empty, so that the effect of having only a left or right heading can be achieved easily enough.

As we will see, an initial header can be given after the title page. Afterwards, a new header can be given for each new chapter or section. The header printed on a page is the one which is in effect at the end of the current page. So that the header will be that of the last section starting on the page.

Table Of Contents Tag

If you place the `<toc>` tag, a *table of contense* will be generated, by looking the section heading, and adding references.

> In a hyperref document, this might be hyperrefs, in a LaTeX document you will come to see the pagenumbers.

Only the sections major to the `sect3` will be included.

List Of Figures Tag

If you place the `<lof>` tag, a *list of figures* will be generated, by looking the captions of the figures, and adding references.

List Of Tables Tag

If you place the `<lot>` tag, a *list of tables* will be generated, by looking the captions of the tables, and adding references.

Body

Here you place various sections according section Sectioning. There is no *body tag*. The body starts with the first *chapter*, *section* or *paragraph*.

Appendix Tag

In the end of the article you can place the `<appendix>` tag

> Really you shouldn't think about people (e.g. m.d.s knifing your belly here.

, wich starts a area of appended sections. The `appendix` tag implies a different section numbering type to the following section tags.

Bibliography Tag

It's intended to gather all the `<cites>` and `<ncites>` you used within your document. The `<biblio>` tag will be replaced by a *bibliography* according the mapping type of the document, maybe by hyperrefs maybe by section numbers or anything wich might be useful.

> Until now I've not been able to create a `.bbl` file, so I wasn't able to verify.

Footnote Tag

A *footnote* may be place in any spot of your document. Exactly the spot in yout document where you are placing the `<footnote>` tag should be the one where the reference to the tagged text shuld be rendered. It should be used for additional information, wich is not necessary for understanding the primary purpouse of yor document but might be usefull, interesting, or funny.

Whereas the last one is not always true, even if you try.

anywhere within the article.

4.2 Report Tag

```
<!element report - -
        (titlepag, header?, toc?, lof?, lot?, p*,
         chapt*, (appendix, chapt+)?, biblio?) +(footnote)>
```

The *report* is a document class with a chapter oriented approach. So within a document clasified by a `<report>` tag the toplevel is grouped by the `<chapt>` tag (see Sectioning). The rest of the structure is identical to the *article* class Article Tag.

4.3 Book Tag

```
<!element book  - -
        (titlepag, header?, toc?, lof?, lot?, p*, chapt*,
         (appendix, chapt+)?, biblio?) +(footnote) >
```

You will notice that the *book* element is identical to the *report* Report Tag. So anything valid there is also valid if you classify your document with a `<book>` tag.

4.4 Letter Tag

```
<!entity  % addr "(address?, email?, phone?, fax?)" >

<!element letter - -
        (from, %addr, to, %addr, cc?, subject?, sref?, rref?,
         rdate?, opening, p+, closing, encl?, ps?)>
```

Also the purpose of the *letter* document class should be quite self explaining. Place a `<letter>` tag if you want to write one.

The letter's tags ar described in table Tags in a letter

tag	mandatory	what's it
from	yes	from sender
address	no	sender's address
email	no	sender's email
phone	no	sender's phone
fax	no	sender's fax
to	yes	receiver
address	no	receiver's address
email	no	receiver's email
phone	no	receiver's phone

fax	no	receiver's fax
cc	no	carbon copy
subject	no	letters subject
sref	no	sender's reference
rref	no	receiver's reference
rdate	no	received date??
opening	yes	opening
paragraphs	yes	see Paragraphs
closing	yes	closing
encl	no	enclosure
ps	no	post scriptum

Tags in a letter

4.5 Telefax Tag

```
<!element telefax - -
        (from, %addr, to, address, email?,
         phone?, fax, cc?, subject?,
         opening, p+, closing, ps?)>
```

Overall the structure is same to the *letter* class. The only difference is that with the `<telefax>` tag the receiver's `<fax>` tag becomes mandatory.

Should be obvious why.

4.6 Slides Tag

```
<!element slides - - (slide*) >
```

The *slides* class is intended for overhead slides and transparencies. So the structure of a document classified by a `<slides>` tag is a very simple one. It contains single slide(s) startes by a `<slide>` tag. Nothing else. If not explicitly written the first *slide* is started implicitly.

Slide Tag

```
<!element slide - o (title?, p+) >
```

A `<slide>` tag is only allowed within the *slides* document class. A *slide* may contain:

A *title* (see section The Title Tag) and one or more *paragraph*s (see section Paragraphs). That's all.

4.7 Note Tag

```
<!element notes - - (title?, p+) >
```

Intended as a class for personal notes the structure is even more simplified than the *slides* document class (see The Slide Tag). After classifying a document with the `<notes>` tag only a *title* (see section The Title Tag) and one or more *paragraph*s (see section Paragraphs) are allowed.

4.8 Manual Page Tag

```
<!element manpage - - (sect1*)
        -(sect2 | f | %mathpar | figure | tabular |
          table | %xref | %thrm )>
```

This document class is intended for writing *manual pages*, fitting the need of the `man` programm. In a document classified by a `<manpage>` tag the topleve section tag is the `sect1` tag (see section Sectioning), for easy pasting manual pages into an *article* or *book* document class. The exception here to the nortmal sectioning is, that there is only one subsection level allowed (`sect2`).

5. Inlines

```
<!entity % inline
        " (#pcdata | f| x| %emph; |sq| %xref | %index | file )* " >
```

Inlines may occure anywhere within the text, and doesn't have any influence to the textflow or logical structure of the document.

#pcdata
: *Parsed character data* is just normal written text within the flow wich may contain other inlines.

f
: Inline *mathematical formulas* according to the `maths.dtd`. See The Formula Tag.

x
: The *external* tag wich is bypassing the parser. Tagged data walks directly into the mapped file. See chapter The External Tag for detailed information.

%emph;
: *Emphasizes* of the text. See chapter Emphasizes.

sq
: *Shortquotes* within the textflow. See chapter The Short Quote Tad.

%xref
: *XReferecnces* within the text or external references. See chapter Labels and References.

%index
: Again I can't explain this one. If you can, please mail.

file
: Again I can't explain this one (I only could guess about picture files in eps). If you can, please mail.

6. Sectioning

```
<!element chapt - o (%sect, sect*) +(footnote)>
<!element sect  - o (%sect, sect1*) +(footnote)>
<!element sect1 - o (%sect, sect2*)>
<!element sect2 - o (%sect, sect3*)>
<!element sect3 - o (%sect, sect4*)>
<!element sect4 - o (%sect)>
```

The *sectioning*

> Also the `chapt` tag is a *sectioning* tag.

is done by the according elements, forming the section tree. They are bringing the various paragraphs within our document to follow a nice tree. The top level tag and the allowed depth is varying with the *document class* (see section The Document Class).

The normal hierarchy is

```
chapt
    sect
        sect1
            sect2
                sect3
                    sect4
```

Just take a book, look the table of conetents and you will see.

Each of the tags out of the *sectionings* has nearly the same syntax. All of them owe a *heading*. The `heading` tag is placed implicitly if you don't note it down. Also the each of the sectioning tags may contain a `header` tag, changing the current document header (see section The Header Tag).

Within the you may place subordinate sections and *paragraphs* (see Paragraphs).

Some of the sectioning tags may only appear in special document classes (Document Classes).

Hint:

> It's wise to place a *label* tag after the text of the *section* tag, even if you don't want to refer to the section Labels and references. Later when your document grows you might want to.

7. Paragraphs

```
<!entity % sectpar
        " %par; | figure | tabular | table | %mathpar; |
          %thrm; | %litprog; ">

<!entity % par
        "  %list; | comment | lq | quote | tscreen " >

<!entity % litprog " code | verb " >
```

Each of the here described tags form a paragraph.

For obvious reason a paragraph is normally

> The behaviour of the exceptions `figure` and `tabular` are explained there.

starting and ending with a new line.

> How else you would notice it's a paragraph ?

There are some tags, wich always form a paragraph, and one way to form a paragraph implicitly. There are various types of paragraphs, because not every type of paragraph is allowed to appear in every document class in every place.

The different types of paragraphs are explained in the next sections. For more details about `%litprog;` see Literate Programming.

7.1 Normal Paragraph

Normal paragraphs can be formed in two ways:

Paragraph tag

The `<p>` tag is starting a new *paragraph*. This tag is mandatory if you want to finish a section header without explicitly closing the `sect` tag. In this case `<p>` tag then closes the `<sect>` tag automatically.

Empty Newline

A empty line between two paragraph is implicitly starting a new *paragraph*. Take care within `descriptive` lists. There a empty `<tag>` tag will not be paragraphed by an empty line.

7.2 List-like Paragraphs

```
<!entity % list
        " list | itemize | enum | descrip " >
```

This four tags indicate the starting of a list-like paragraph. Within each of the lists the single items are separated by an *item tag*.

```
<!element item o o ((%inline; | %sectpar;)*, p*) >
```

As you can see, a item may again contain paragraphs (and therefore also may contain other lists - even of a different type).

List Tag

```
<!element list - - (item+)>
```

The *list tag* will be mapped to a nacked list without bullets, numers or anything else.

To see it, I place a small example:

```
<list>
<item>A point
<item>Another one
<item>Last
</list>
```

Will look (depending on the mapping) like:

- A point
- Another one
- Last

Itemize Tag

```
<!element itemize - - (item+)>
```

The *itemize tag* will be mapped to a list with bullets, wich is usually place for lists where the order of the items is not important.

A small example:

```
<itemize>
<item>A point
<item>Another one
<item>Last
</itemize>
```

Will look (depending on the mapping) like:

- A point
- Another one
- Last

Enum Tag

```
<!element enum - - (item+)>
```

The *enum tag* will be mapped to a list with numbers.

A small example:

```
<enum>
<item>A point
<item>Another one
<item>Last
</enum>
```

Will look (depending on the mapping) like:

1. A point
2. Another one
3. Last

Descrip Tag

```
<!element descrip - - (tag?, p+)+ >
```

The *descrip tag* will be mapped to a descriptive list. The concept here is a little bit different than with the other types of lists mentioned above.

Here you place a *tag* (this time the tag's name is really litteraly `tag`) wich is described later on.

A small example:

```
<descrip>
<tag/sgml/structured general markup language.
<tag/html - hypertext markup language/
A sgml implementation.
It contains some concepts about linking information together in a very
convenient way.
This made it to be so successful and to become the standard for documents
published by the internet.
<tag/internet/A worldwide connected internet (internet here as a
technical term)
</descrip>
```

Will look (depending on the mapping) like:

sgml
: structured general markup language.

html - hypertext markup language
: A sgml implementation. It contains some concepts about linking information together in a very covenient way. This made it to be so successfull and to become the standard for documents published by the internet.

internet
: A worldwide connected internet (internet here as a technical term)

7.3 Figures and Tables

The `<figure>` and the `<table>` tags form very special paragraphs. Not always they stay within the normal textflow. Both of the tags can hold a `loc` (*loction*) attribute wich is telling how to handle the flow of this special paragraph.

The value of the `loc` attribute is a string of up to four letters, where each letter declares a location at which the figure or table **may** appear, as described in table Table Locations.

h	here	At the same location as in the SGML file
t	top	At the top of a page
b	bottom	At the bottom of a page
p	page	On a separate page only with figures and tables

Table Locations

The default value of the loc attribute is `top`.

Table Tag

```
<!element table   - - (tabular, caption?) >
```

As you can see a *table* consists of the <table> tag itself, including a <tabular> tag and a optional <caption> tag.

The <tabular> tag may also be placed without a <table> tag so it is described in detail in it's own section (see Tabular Tag).

The *caption* is used also to place the entry for the *list of tables* if you stated one (see The List Of Tables Tag).

A short example will show how it's working together.

```
<table loc="ht">
<tabular ca="lcr">
Look|this|table@
Isn't|it|nice@
1.234|mixed|columns
</tabular>
<caption>A sample table
</table>
```

Look	this	table
Isn't	it	nice
1.234	mixed	columns

A sample table

The *caption* "A sample table" would be the name in the *list of tables*.

Figure Tag

```
<!element figure - - ((eps | ph ), img*, caption?)>
```

The usage of the <figure> tag is equivalent to the <table> tag. Instead of the <tabular> tag you place either a <eps> or a <ph> tag.

Encapsulated Postscript(TM) Tag

```
<!attlist eps
        file cdata #required
        height cdata "5cm"
        angle cdata "0">
```

The <eps> tag is intended for including a external file in *encapsulated postscript(TM)* format into the document.

The attributes of the `<eps>` tag are:

file
: The `file` attribute needs the *file name* of a encapsulated postscript(TM) file ending with a `.ps` suffix. The mandatory `.ps` suffix must not be written.

height
: The *height* of the space the file is zoomed to. If you don't specify it defaults to 5cm. Take care that there's no spcae between the number and the length unit (`i`, `cm`).

angle
: The *angle* is given in normal degrees (0-360) and as the number is increasing the file is rotated counter clockwise.

A example:

```
<figure loc="here">
<eps file="logo" height="4cm" angle="15">
<img src="logo.gif">
<caption>A included encapsulated postscript&trade;
</figure>
```

The *img* tag is ignored by LaTeX-mapping and useful for html, 'cause most browsers don't know about eps.

A included encapsulated postscript(TM) file.

The *caption* here would go to the *list of figures* as decribed in section The List Of Figures Tag.

Placeholder Tag

```
<!attlist ph
        vspace cdata #required>
```

This tag doesn't place anything but keeps a clean space for good old manual picture pasting. The space kept free is destined by the `vspace` attribte. **Caveat:** The numerical argument for the `vspace` attribte needs a unit directly behind the number. Don't leave a space there (same as for the `height` attribute in Encapsulated Postscript(TM) Tag.

```
<figure loc="ht">
<ph vspace="5cm">
<caption>A blank space.
</figure>
```

Results to:

A blank space for gluing a photo

At this point you might want to look for your scissors and the glue.

7.4 Tabular Tag

```
<!element tabular - -
       (hline?, %tabrow, (rowsep, hline?, %tabrow)*, caption?) >
```

The <tabular> tag is interpreted as an own paragraph, if it is written standalone. Together with a <table> tag it gets part of the paragraph of the <table> tag (see Table tag).

Within the tabular tag you have rows an collumns wich are separating the text. You have to have at least one collumn and one row.

> Wouldn't be very usefull otherwise.

The <tabular> tag has a mandatory ca attribute for *collumn allignement*. The collumn allignement holds a single character for each collumn in their order from left to right. The chracters you may place per collumn described in table Collumns allignements

char	alignment
l	left
c	centered
r	right

Column alignments

In theory you should be able to place a | into the ca attribure for drawing a horizontal line for separating two collumns. The problem: It doesn't work. The parser accepts it nicely, only the LaTeX output will map | to {$|$} wich is of course the set for four collumns with invalid collumn allignement for all four collums. I'll try to figure out what to do about it.

The columns within the <tabular> tag are separated by a *collumn separator*, the <colsep> tag. The character | is translated to <colsep> so you can also place that one instead

> Less typing, more fun.

.

What's valid for collumns is also valid for rows. You separate the by a *row separator*, the <rowsep> tag. The character @ is translated to <rowsep>.

Optional you can place a *horizontal line* with the <hline> tag. Take care with that one: The SGML tools will parse it nicely weather you place it in front of the row you want under the line, or behind the end of the row you want over it. But the only place to write it without causing the parser to shout "error" is to write it dircetly and without space or newline behind the row separator.

```
<tabular ca="lcr">
Look|this|table@<hline>
Isn't|it|nice@
1.234|mixed|columns@
</tabular>
```

Results in table Sample table for tabular tag

Look	this	table
Isn't	it	nice
1.234	mixed	columns

Sample table for tabular tag

Attention:

In LaTeX mapping everything works nice if you place a *tabular tag* without a *table tag*, only in the other mappings (e.g. html) it will be messed up.

7.5 Mathematical Paragraph

```
<!entity % mathpar " dm | eq " >
```

A *mathematical paragraph* consits either of a *displayed formula*, tagged by <dm>

No, sorry, not for Deutschmark! ;-)

or an *equation*, tagged by <eq>. They work very much the same.

Both of these tags contain a mathematical formula. See Mathematical Formulas for the tags valid here.

Note:

Because neither Netscape nor Microsoft has seen any need to add mathematical mappings to their browsers (like demanded and defined by *w3c*), there is no nice way of mapping, or at least displaying the math stuff in html. So if you view the online version, feel free to wonder what nonsense this man is telling here. Might be you should take a glance at the postscript version.

Displayed Formula Tag

This tag displays a *mathematical formula* as a *paragraph*. The formula is mapped centered as a single line

No guarantee for that. You know: Mapping is a matter of taste.

.

```
<dm>(a+b)<sup/2/=a<sup/2/+2ab+b<sup/2/</dm>
```

Is mapped to: $(a+b)^2=a^2+2ab+b^2$

Equation Tag

```
<dm>(a+b)<sup/2/=a<sup/2/+2ab+b<sup/2/</dm>
```

Is mapped to: $(a+b)^2=a^2+2ab+b^2$

7.6 Theorem Paragraph

```
<!entity % thrm
        " def | prop | lemma | coroll | proof | theorem " >

<!element def - - (thtag?, p+) >
<!element prop - - (thtag?, p+) >
<!element lemma - - (thtag?, p+) >
<!element coroll - - (thtag?, p+) >
<!element proof - - (p+) >
<!element theorem - - (thtag?, p+) >
```

As you can see the different types of *theorem* paragraphs are nearly identical. The only exception wich is a little bit different is the *proof* wich doesn't own a `thtag`. For all the others the `thtag` is giving the *tag* of the theorem paragraph.

Yust try to use that one, wich is fitting the meaning of what you are typing.

```
<thrm>
<thtag>Alexander's thrm</thtag>
Let <f>&lt;fi/G/</f> be a set of non-trivially achievable subgoals
and &mu; an order on <f>&lt;fi/G/</f>. &mu; is abstractly
indicative if and only if it is a linearization of
<f><lim><op>&mu;</op><ll><fi/G/</ll><ul>&ast;</ul></lim></f>.
</theorem>
```

The `thrm` is replaced by the adequate tag.

Maybe somebody knowing about mathematics would be shocked about my abuse of the types, but I'm lazy so I simply copied the examples:

Definition (`def`): Alexander's Definition

Let G be a set of nontrivially achievable subgoals and μ an order on G. μ is abstractly indicative if and only if it is a linearization of μG

*.

Proposition (`prop`): Alexander's Proposition

Let G be a set of nontrivially achievable subgoals and μ an order on G. μ is abstractly indicative if and only if it is a linearization of μG

*.

Lemma (`lemma`): Alexander's Lemma

Let G be a set of nontrivially achievable subgoals and μ an order on G. μ is abstractly indicative if and only if it is a linearization of μG

*.

Corollation (`coroll`): Alexander's Corollary

Let G be a set of nontrivially achievable subgoals and μ an order on G. μ is abstractly indicative if and only if it is a linearization of μG

*.

Alexander's Theorem

Let G be a set of nontrivially achievable subgoals and μ an order on G. μ is abstractly indicative if and only if it is a linearization of μG

*.

The proof is just the same without the `thtag`:

Let G be a set of nontrivially achievable subgoals and μ an order on G. μ is abstractly indicative if and only if it is a linearization of μG

*.

7.7 Code and verbatim Paragraphs

Both tags from a paragraph and have very similar behavior. Inside this tags most special characters don't need their named form as in section Named Symbols. The exceptions are:

1. &etago; -> </ -> `end of tag open`

Maybe later the list will grow.

In difference to the normal paragraph mapping white-spaces and newlines will be mapped literally (as you write them in your source).

Also (with respect to manual layout) the font for mapping will be a non-proportional one.

> See the difference between IIWW and `IIWW`.

Note:

> Aggain, I'm neither a native speaker not I love mathematics a lot. So I just placed some nonsense, wich might cause headache and grey hair for people who want to use this document for learning to formulate mathematical or physical theories.
>
> Feel free to send better examples.

Code Tag

```
<!element code - - rcdata>
```

Use the *code tag*, if you want to write sourcecode example within your text.

A code sample

<code>

```
#include <stdio.h>
int main() {
    printf("Hello world");
    return 1;
}
```

</code>

Verbatim Tag

```
<!element verb - - rcdata>
```

Use the *verbatim tag* for anything else than sourcecode (use Code Tag for this) which needs the good old whitespace padding, like terminal hardcopy, ASCII-Graphics etc.

A verb sample

<verb>

```
/////////
| *   * |
|   |   |
| <---> |
 \_____/
```

</verb>

8. Inline Tags

Here the abstract *inlines* are broken down until only true and usable tags will remain. Let's recall:

```
<!entity % inline
        " (#pcdata | f| x| %emph; |sq| %xref | %index | file )* " >
```

Inlines don't have a influence to paragraphing, sectioning or document classing. Just modifying text within it's normal flow.

8.1 Emphasizes

```
<!entity % emph
        " em|it|bf|sf|sl|tt|cparam " >
```

The *emphasizes* are gathering the tags for emphasizing inline text.

The different types of emphasizes are:

em -> The Emphasize Tag
: I hate to be redundant but I have to say: The *emphasize* tag you place for emphasized text. Normally it's mapped to italic letters. So if you write `<em/a emphasized text/` it will be mapped to *a*

emphasized text.

`it` -> The Italic Tag

The *italic* tag you place for a cursive mapping. If you write `<it/a italic text/` it will be mapped to *a italic text*.

`bf` -> The Boldface Tag

The *boldface* tag you place for a bold mapping. If you write `<bf/a bold text/` it will be mapped to **a bold text**.

`sf` -> The Swissfont Tag

I know that Tom Gordon from GMD is telling that this is the `sans serif` tag. My interpretation of the sf is *swissfont* wich for me is more easy to remember. This is mapping the inlined text to a font wich is out of the helvetica family. So `<sf/a swissfont text/` will be mapped to a swissfont text.

`sl` -> The Slanted Tag

I think I skip the explanation. `<sl/a slanted text/` will be mapped to *a slanted text*.

`tt` -> The Terminaltype Tag

Text tagged with *terminaltype* will be placed inline, just like all the other text within a paragraph. It will not be included into source output if you are workink as described in section Literate Programming, even if it's looking like typed code. `<tt/a terminal typed text/` will be mapped to `a terminal typed text`.

8.2 Short-quote Tag

Normally this one could be viewed the same level like one of the *emphasize* tags, but the definition of the linuxdoc dtd is placing it same level like the emphasizes, and so I do.

The `shortquote` tag is a inline quotation, not forming an own paragraph. The text `<sq/a short quote/` is mapped to "a short quote".

8.3 Formula Tag

The *formula* tag allows us to note down a mathematical formula within the normal text, not appearing in an own line. So the text `<f>x=y<sup>2</sup></f>` will be displayed as $x=y^2$. See Mathematical Fomulas for the tags valid within the *formula*.

8.4 External Tag

The *external tag* is passing the tagged data directly through the parser, without modifying it. E.g. to LaTeX.

9. Mathematical Formulas

They can appear with in the tags listed in table Places of Mathematical Formulas

tag	description	see
f	inline formula	The Formula Tag
dm	displayed formula	Mathematical Paragraph

eq	equation	Mathematical Paragraph

Places of Mathematical Formulas

If you view this document mapped to html you will notice that html has no nice way of displaying mathematical formulas.

After a little hand parsing the contents of a *mathematical* tag looks like:

```
<!element  xx       - -
        (((fr|lim|ar|root) |
          (pr|in|sum) |
          (#pcdata|mc|(tu|phr)) |
          (rf|v|fi) |
          (unl|ovl|sup|inf))*)>
```

The `xx` stands for `f`, `dm` or `eq`. All of them are the same.

Note:

Because neither Netscape nor Microsoft has seen any need to add mathematical mappings to their browsers (like demanded and defined by *w3c*), there is no nice way of mapping, or at least displaying the math stuff in html. So if you view the online version, feel free to wonder what nonsense this man is telling here. Might be you should take a glance at the postscript version.

9.1 Fraction Tag

```
<!element  fr       - - (nu,de) >
<!element  nu       o o ((%fbutxt;)*) >
<!element  de       o o ((%fbutxt;)*) >
```

So what we see from it is, that a *fraction* consits of a *numerator* and a *denumerator* tag, wich again each one can hold a *mathematical formula*.

I think an example will tell you more:

```
<dm><fr><nu/7/<de/13/</fr></dm>
```

results to:

713

In case we want to to place 1/2 instead of the numerator without cleaning it up, we'll type:

```
<dm><fr><nu><fr><nu/1/<de/2/</fr></nu><de/13/</fr></dm>
```

Which results to:

1213

9.2 Product, Integral and Summation Tag

```
<!element  pr       - - (ll,ul,opd?) >
<!element  in       - - (ll,ul,opd?) >
<!element  sum      - - (ll,ul,opd?) >
```

Each of them has a *lower limit* (`ll` tag), a *upper limit* (`ul` tag) and a optional *operand*, where each of them again may consist of a formula. The tags are same in syntax like shown in table Tags with upper-, lower limit and operator.

name	example	result
Product	`<f>y=<pr><ll>i=1<ul>n<opd>x<inf/i/</pr></f>`	$y=\prod_{i=1}^{n} x_i$
Integral	`<f>y=<in><ll>a<ul>b<opd>x<sup/2/</in></f>`	$y=\int_{a}^{b} x^2$
Summation	`<f>y=<sum><ll>i=1<ul>n<opd>x<inf/i/</sum></f>`	$y=\sum_{i=1}^{n} x_i$

Tags with upper-, lower limit and operator

9.3 Limited Tag

```
<!element  lim      - - (op,ll,ul,opd?) >
<!element  op       o o (%fcstxt;|rf|%fph;) -(tu) >
<!element  ll       o o ((%fbutxt;)*) >
<!element  ul       o o ((%fbutxt;)*) >
<!element  opd      - o ((%fbutxt;)*) >
```

You can use that one for operators with upper and lower limits other than products, sums or integrals. The for the other types defined *operator* is destinied by the `op`tag, wich can contain again a mathematical formula.

Bi=0

nx_i

9.4 Array Tag

```
<!element  ar       - - (row, (arr, row)*) >
<!attlist  ar
    ca     cdata    #required >
<!element  arr      - o empty >
<!element  arc      - o empty >
<!entity   arr "<arr>" >
<!entity   arc "<arc>" >
```

Of course a reasonable mathematical document needs a way to describe arrays and matrices. The *array* (`ar`) is noted down equivalent to a *tabular* (see section The Tabular Tag). The differences in handling are:

- No `<hline>` tag.
- The `ca` attribute character `|` is not allowd.
- Columns are not separated by `colsep` tag but with the `arc` tag (*array collumn*).
- Rows are not separated by `rowsep` tag but with the `arr` tag (*array row*).

Again the characters `|` and `@` are mapped to the adequate separator tag, so you really can note a array same way as a tabular.

```
<dm><ar ca="clcr">
a+b+c | uv    <arc> x-y | 27    @
a+b   | u+v   | z   | 134   <arr>
a     | 3u+vw | xyz | 2,978
</ar></dm>
```

Is mapped to:

a+b+c uv x-y 27 a+b u+v z 134 a 3u+vw xyz 2,978

9.5 Root Tag

```
<!element  root     - - ((%fbutxt;)*) >
<!attlist  root
        n cdata "">
```

The *root* is noted down by the `root` tag, wich contains a `n` attribute, holding the value for the "n'th" root.

```
<dm><root n="3"/x+y/</dm>
```

is mapped to:

x+y

9.6 Figure Tag

```
<!element  fi  - o (#pcdata) >
```

With the figure tag you can place mathematical figures. The tagged characters are directly mapped to a mathematical figure. Which character is mapped to which figure you'll find in Mathematical Figures.

9.7 Realfont Tag

```
<!element  rf  - o (#pcdata) >
```

This tag is placing a real font within a mathematical formula.

> I'm really not sure about `rf`. What should it be?

No formula is allowed within that tag.

```
<dm><rf/Binom:/ (a+b)<sup/2/=a<sup/2/+2ab+b<sup/2/</dm>
```

is mapped to:

Binom: $(a+b)^2=a^2+2ab+b^2$

9.8 Other Mathematical Tags

The remaining tags simply modify the tagged formula, without implying any other tag. The effect is shown in table Mathematical tags without included tags

name	tag	example		result
vector	v	<f><v/a/×<v/b/=<v/0/</f>	->	a×b=0
overline	ovl	<f><ovl/1+1/=<ovl/2/</f>	->	1+1=2
underline	unl	<f><unl/1+1/=<unl/2/</f>	->	1+1=2
superior	sup	<f>e=m×c<sup/2/</f>	->	$e=m\times c^2$
inferior	inf	<f>x<inf/i/:=2x<inf/i-1/+3</f>	->	$x_i:=2x_{i-1}+3$

Mathematical tags without included tags

10. Labels and References

```
<!entity % xref
        " label|ref|pageref|cite|url|htmlurl|ncite " >
```

As soon as it´s a little bit more sophisticated a document will need references to other places within the document.

10.1 Label Tag

```
<!element label - o empty>
<!attlist label id cdata #required>
```

If you want to refer to a spot, chapter or section within your document you place a *label tag*.

A example could look like:

```
<sect1>Welcome to the article<label id="intro">
<p>...
```

10.2 Reference Tag

```
<!element ref - o empty>
<!attlist ref
        id cdata #required
        name cdata "">
```

With this tag you can refer to a place within your document labeled as in Label Tag.

The way the reference is mapped in you document again depends to the mapper. May result to a hyper-ref (HTML) or a section number (LaTeX).

10.3 Page reference Tag

```
<!element pageref - o empty>
<!attlist pageref
        id cdata #required>
```

A example for a pageref:

```
<pageref id="intro">
```

In the HTML mapping there is no use for *pageref*, because there are no page numbers. In LaTeX mapping the tag is mapped to the pagenumber of the reffered label.

10.4 Url Tag

```
<!element url - o empty>
<!attlist url
        url cdata #required
        name cdata "" >
```

A example for a *url*:

```
<url url="http://www.gnu.org" name="GNU Organization">
```

GNU Organisation

The mapping to html brings up a hyper-ref in your document. The reference is the value of the *url* attribute, the text standing in the Hyperref is the *name* attribute's value.

In LaTeX mapping this one results to the name followed by the url.

10.5 Htmlurl Tag

```
<!element htmlurl - o empty>
<!attlist htmlurl
        url cdata #required
        name cdata "" >
```

A example for a htmlurl:

```
<htmlurl url="http://www.gnu.org" name="GNU Organization">
```

GNU Organisation

The only difference between this tag and the Url Tag is in the LaTeX mapping.

The LaTeX mapping simply drops the url attribute and emphasizes the name.

In all other cases it's absolutely the same as the *url tag*.

10.6 Cite Tag

```
<!element cite - o empty>
<!attlist cite
        id cdata #required>
```

AFAIK this one need´s bibTeX to work nicely. So I'm terribly sorry, but I was not jet able to make use of it. For that reason for sure I'm the wrong one to explain about it.

10.7 Ncite Tag

```
<!element ncite - o empty>
<!attlist ncite
        id cdata #required
        note cdata #required>
```

Same as Cite Tag.

11. Indices

```
<!entity % index "idx|cdx|nidx|ncdx" >

<!element idx - - (#pcdata)>
<!element cdx - - (#pcdata)>
<!element nidx - - (#pcdata)>
<!element ncdx - - (#pcdata)>
```

tag	my translation
idx	index
cdx	code index (terminaltype index)
nidx	invisible index
ncdx	invisible code index (terminaltype index)

Index elements

The index tags serve for making a index of your document. They are only useful if you want do LaTeX mapping. They only differ very slightly as mentioned in table Index elements.

11.1 Including a index

There are two ways to include indices into your document. Look at both and decide.

Manually

1. Set the opts attribute of your document class to contain the packages *makeidx*. You do that by: `<article opts="makeidx">`.
2. Mark all the words you want to be in the index later with a *idx tag* or *cdx tag*. If the word you want to index to a location in your document is not within the text you simply write it at the location you want to index with the *nidx tag*. It´s like the normal *idx* only the tagged text will be silently dropped in the normal document.
3. Process your file with makeindex `sgml2latex -m mydocument.sgml`.
   This will produce an additional `mydocument.idx`.
4. Process `mydocument.idx` with the `makeindex` command like `makeindex mydocument.idx`.
   This will produce an additional `mydocument.ind`.
5. To include the now generated index in your document you process your document with `sgml2latex -o tex -m mydocument.sgml`.
   This results in output of `mydocument.tex`.
6. Edit `mydocument.tex` with the editor of your choice.
   You look for the line `\end{document}` (should be somewhere close to the end of the file) and insert the text `\printindex` bevor this line.
7. Process the modified file with `latex mydocument.tex`.
   This gives you the final `mydocument.dvi` wich aggain you might process with `dvips` to generate a postscript document.

A lot of a mess, ain't it?

Hacked

I'm currently working on a patch to the sgmltools to automate the inclusion and generation of a index. To find out the current state see http://www.bnhof.de/~uwe/lnd/indexpatch/index.html.

12. Literate Programming

```
<!entity % litprog " code | verb " >
```

This one is a funny thing. It's the idea of not to write some comment text within a program, and might be to take later some special tools, to extract the text

> Think of `perlpod`.

, but to write a big document and later to extract the code from it.

> People who don't like to document their code will not appreciate.

The principle is: All text within `verb` and `code` tags, will be gathered into a sourcefile.

That's it, because for now I don't remember the name of the tool doing thatone.

Named Characters

14.2 Named Whitespaces

There is a small number of whatever you want to name it. The look like named characters, but will be printed not always, or not at all.

thinsp
: Thin space:

  `d D` ->d D

emsp
: Emphasized space: `d D` -> d D

ensp
: Normal space: /d D/ -> d D

nbsp
: No break space: A spaces at wich the line is not allowed to be broken. Two words separated by a `nbsp` will be treated by parser and mapper to be a single long one.

shy
: Suggest Hyphen: If the mapper is up to break a word, with has the `shy` tag inside, it will probably do the wordbreak at the place of the `shy` tag and place a *hyphen* instead. If no wordbreak is necessary the `shy` expands to nothging at all.

15. Mathematical Figures

a-ab-bc-cd-de-ef-fg-gh-hi-ij-jk-kl-lm-mn-no-op-pq-qr-rs-st-tu-uv-vw-wx-xy-yz-z	―	A-AB-BC-CD-DE-EF-FG-GH-HI-IJ-JK-KL-LM-MN-NO-OP

Mathematical Figures

The special mappings for characters you might use for building up mathematical figures are shown in table Mathematical Figures.

16. Linuxdoc dtd Source

This is the `linuxdoc.dtd` used to parse this document. The revision log, revision comments and a few redundant lines are taken out for saving paper and screenspace.

```
<!-- This is a DTD, but will be read as -*- sgml -*-   -->
```

```
<!-- ================================================ -->
<!-- $Id$

     This is LINUXDOC96 DTD for SGML-Tools.

     This was LINUXDOC.DTD,
     a hacked version of QWERTZ.DTD v1.3 by Matt Welsh,
     Greg Hankins, Eric Raymond, Marc Baudoin and
     Tristan Debeaupuis; modified from QWERTZ.DTD by
     Tom Gordon.

<!entity % emph
